

PROTECTION DEVICE FOR A TURBINE STATOR

The present invention relates to a protection device for a turbine stator.

10 A gas turbine is a rotating thermal machine which converts the enthalpy of a gas into useful work, using gases coming from a combustion and which supplies mechanical power on a rotating shaft.

15 The turbine therefore normally comprises a compressor or turbo-compressor, inside which the air taken from the outside is brought under pressure.

Various injectors feed the fuel which is mixed with the air to form a air-fuel ignition mixture.

20 The axial compressor is entrained by a so-called turbine, or turbo-expander, which supplies mechanical energy to a user transforming the enthalpy of the gases combusted in the combustion chamber.

25 In applications for the generation of mechanical energy, the expansion jump is subdivided into two partial jumps, each of which takes place inside a turbine. The

high-pressure turbine, downstream of the combustion chamber, entrains the compression. The low-pressure turbine, which collects the gases coming from the high-pressure turbine, is then connected to a user.

5 The turbo-expander, turbo-compressor, combustion chamber (or heater), outlet shaft, regulation system and ignition system, form the essential parts of a gas turbine plant.

As far as the functioning of a gas turbine is concerned, it is known that the fluid penetrates the compressor through a series of inlet ducts.

In these canalisations, the gas has low-pressure and low-temperature characteristics, whereas, as it passes through the compressor, the gas is compressed and its
15 temperature increases.

It then penetrates into the combustion (or heating) chamber, where it undergoes a further significant increase in temperature.

The heat necessary for the temperature increase of
20 the gas is supplied by the combustion of gas fuel introduced into the heating chamber, by means of injectors.

The triggering of the combustion, when the machine is activated, is obtained by means of sparking plugs.

At the outlet of the combustion chamber, the high-
25 pressure and high-temperature gas reaches the turbine,

through specific ducts, where it gives up part of the energy accumulated in the compressor and heating chamber (combustor) and then flows outside by means of the discharge channels.

5 In the inside of a turbine there is a stator, equipped with a series of stator blades in which a rotor, also equipped with a series of blades (rotor), is housed and is capable of rotating, said stator being rotated as a result of the gas.

10 The protection device of the stator, also known as "shroud", together with the platform of stator blades, defines the main gas flow.

 The function of the shroud is to protect the outer cases, which are normally made of low-quality materials and therefore have a low resistance to corrosion, from
15 oxidation and deterioration.

 The shroud generally consists of a whole ring, or is suitably divided into a series of sectors, each of which is cooled with a stream of air coming from a compressor.

20 The cooling can be effected with various techniques which essentially depend on the combustion temperature and temperature decrease to be obtained.

 The type of protection device to which the present invention relates comprises a series of sectors, assembled to form a ring, each of which has a cavity situated
25

on the outer surface of each sector.

In the case of machines with a high combustion temperature, the most widely used cooling technique is that known as "impingement".

5 According to this technique, a sheet is fixed, preferably by means of brazing, on each cavity of each sector, said sheet equipped with a series of pass-through holes through which fresh air coming from a compressor is drawn for the cooling of the shroud itself, in particular
10 by the impact of said air on the bottom surface of said cavity and its subsequent discharge from a series of outlet holes situated in each sector, not shown in the figures.

In spite of these expedients, even if an efficient
15 cooling is effected, the shroud and therefore also each of its sectors, is subject to deformation due to thermal gradients and to the operating temperature of the turbine which create a deformed configuration different from that at room temperature, i.e. with respect to a rest configuration
20 in which the turbine is not operating.

As a result of the thermal gradients which develop during the functioning of the turbine, a non-uniform deformation is created of the shroud and in particular of each of its sectors.

25 Shrouds are therefore normally produced using super-

alloys coated with suitable materials for limiting the temperatures thereon.

A first disadvantage is that this causes deformations at the operating temperatures which limit deformations but do not allow the clearances to be reduced to
5 the minimum for the danger of possible friction between the shroud and blades with which the rotor is equipped.

Another disadvantage is that by increasing the rigidity of the shroud, the stress increased by the thermal
10 gradients also increases, with a consequent brusque reduction in the useful life of the shroud itself.

This causes a deterioration in the reliability of the gas turbine in which the shroud is installed and also the maintenance costs as the shroud must be substituted
15 more frequently to keep the turbine in a good state and avoid sudden stoppages.

An objective of the present invention is to provide a protection device for a turbine stator which allows a reduction in the clearances and at the same time main-
20 tains a high useful life.

A further objective is to provide a protection device for a turbine stator which has a high rigidity maintaining low stress on the protection device itself.

Another objective is to provide a protection device
25 for a turbine stator which increases the performances of

the turbine itself.

Yet another objective is to provide a protection device for a turbine stator which is simple and economical.

These objectives according to the present invention
5 are achieved by providing a protection device for a stator of a gas turbine as specified in claim 1.

Further characteristics of the invention are indicated in the subsequent claims.

The characteristics and advantages of a protection
10 device of a stator of a gas turbine according to the present invention will appear more evident from the following illustrative and non-limiting description, referring to the schematic drawings enclosed, in which:

figure 1 is a raised longitudinal sectional view of
15 a sector of a preferred embodiment of a protection device of a gas turbine rotor according to the present invention;

figure 2 is a raised sectional radial view of the sector of figure 1;

20 figure 3 is a raised sectional side view according to the line III-III of figure 2.

With reference to the figures, these show a protection device for a turbine stator comprising a series of annular sectors 12 which can be coupled by connection
25 means, each sector 12 comprising a first side surface 13

which has at least one cavity 14 having a bottom 15, each sector 12 comprises at least one stiffening rib 16 positioned inside said at least one cavity 14 and having a variable section in a longitudinal direction to modulate the rigidity of each sector 12.

Furthermore, each bottom 15 of said at least one cavity 14 is also convex to modulate the rigidity of each sector 12.

Said bottom 15 is preferably convex in a circumferential and/or axial direction, so as to obtain a variable section of the shroud.

This produces a variable rigidity of the shroud which, during the functioning of the turbine, has a uniform circumferential and/or axial deformation and therefore a low state of stress.

At the same time, minimum clearances are obtained, which are such as to guarantee an increase in the efficiency of the turbine, also maintaining a high useful life of the shroud.

Said convex bottom 15 preferably has an apex which, in an axial section, has an axial curvature radius 70 which, adimensionalised with respect to the radius of the rotor, i.e. divided by the radius of the rotor, has a value preferably ranging from 0.221 to 0.299.

Said adimensionalised axial curvature radius 70 is

preferably 0.260.

In a radial section, said apex preferably has a circumferential curvature radius 60 which, adimensionalised with respect to the radius of the rotor, i.e. divided by
5 the radius of the rotor, has a value preferably ranging from 0.365 to 0.494.

Said adimensionalised circumferential curvature radius 60 is preferably 0.429.

Said apex in an axial section preferably has a distance 80 from one end of said at least one cavity 14,
10 said distance 80 adimensionalised with respect to an axial length of said at least one cavity 14, has a value ranging from 0.142 to 0.192.

Said adimensionalised distance 80 is preferably
15 0.167.

With respect to the axis of the turbine 70, said rib 16 along an axial direction is preferably tilted by an angle 50 preferably ranging from 3.162° to 4.278° .

Said angle 50 is preferably 3.72° .

20 In other words, a resistant axial section of the rib 16 varies linearly along the axis of the turbine 70, so as to balance the thermal gradient along the axis 70 of the turbine.

Said rib 16 has a maximum axial height 90 which,
25 adimensionalised with respect to the axial length of the

at least one cavity 14, i.e. divided by said axial length, has a value preferably ranging from 0.133 to 0.180.

Said adimensionalised maximum axial height 90 is
5 preferably 0.156.

Each sector 12 also comprises a sheet 20 equipped with a series of pass-through holes 21 for the introduction of air for the cooling of the sector 12 itself.

Said sheet is fixed to the corresponding sector 12,
10 or is preferably integral therewith, so as to cover the at least one cavity 14.

It can thus be seen that a protection device for a turbine stator according to the present invention achieves the objectives specified above.

15 The protection device for a turbine stator of the present invention thus conceived can undergo numerous modifications and variants, all included in the same inventive concept.

Furthermore, in practice, the materials used, as
20 also the dimensions and components, can vary according to technical demands.
